**Abstract.**We have studied the electrical resistivity as a function of temperature in Micro-bridges of  $YBa_2Cu_3O_{7-\delta}$  deposited by laser ablation on the  $SrTiO_3$  substrate face, around superconducting transition region in different magnetic fields. The activation energy  $U_0$  was determined and discussed using the Arrhenius relation. The irreversibility line  $B_{irr}$  and the upper critical field  $B_{c2}$  were obtained using 10% and 90% criteria of the normal-state resistivity value from  $\rho$  (T) curves. A phase diagram of the studied sample is constructed showing the Tg glass line and a very broad vortex-liquid phase regime.

## **1** Introduction

The vortex dynamics in type II superconductors is of great interest and is the subject of much work. Experimental, theoretical and also simulation work indicate that these systems can have new dynamic phases and transitions between different flow regimes depending on the driving force that tends to set the vortex lattice in motion [1].

YBCO is one of the most interesting superconductors as its upper critical magnetic field and critical current density is quite large among HTSC. Many researchers have studied their electrical transport properties dependent on the magnetic field of hightemperature superconductors. As an example of transport properties, the electrical resistivity versus temperature  $\rho(T)$  is strongly influenced by the application of magnetic field [2–9].

In this paper, we studied the dependence of the activation energy of different samples of  $YBa_2Cu_3O_{7-\delta}$  film as a function of the magnetic field and the temperature. An accepted method for probing this dependence is to measure the resistive transition in various magnetic fields applied and the determination of activation energy using the conventional Arrhenius relationship. The activation energy  $U_0$  values can be directly deduced from the slope of the Arrhenius curve. The resistivity curves allowed to identify a vortex - glass (VG) phase and to obtain the value of the glass transition temperature  $T_g$ . A phase diagram of the studied samples was determined as a function of the evolution of the vortex-glass transition temperature  $T_g$ .

## 2 Experimental procedure

The sample used is in this work is a film of  $YBa_2Cu_3O_{7-\delta}$  deposited at 750°C on a SrTiO<sub>3</sub> substrate by pulsed laser deposition. This film contains three samples of different geometries, each with a form of micro-bridge (width × length):  $10\mu$ m×575µm;  $50\mu$ m×575µm;  $100\mu$ m×300µm. The studied film was developed in the GREYC laboratory in France by Professor L. Méchin. Below are the conditions of samples preparation:

- Holder substrate temperature T = 700°C (corresponding to a real substrate temperature of about 750°C).
- O2 dynamic pressure during the deposit:  $P(O_2)=0.5mbar$ .
- Laser: 220 mJ/3Hz.
- Speed: 0.06 nm/shot (200 nm for 3000 shots).
- The cooling system is formed by a plateau for 30 minutes at 500°C and a pressure of 700mbar.
- Target-substrate distance is 5cm.

It should be noted that deposit conditions of  $YBa_2Cu_3O_{7-\delta}$  depend on the deposit structure used. They are obviously similar but, for example, the temperatures and the pressures of deposit cannot be directly compared because their values depend on the geometry of the furnace, the position of the thermocouple compared to the substrate.

## 3 Results and discussion

### 3.1 Temperature dependence of resistivity

Figure 1 represents temperature dependence of the resistivity for the micro-bridges of  $YBa_2Cu_3O_{7-\delta}$  :(a)  $10\mu m \times 575\mu m$ , (b)  $50\mu m \times 575\mu m$  and (c)  $100\mu m \times 575\mu m$  near the superconducting transition Tc region at B=0,2 and 7 T, the field is oriented parallel to the c-axis (B//c). From the figures, two important behaviours have been observed. In zero magnetic field, the prepared samples exhibit a sharp transition to zero resistivity at critical temperature Tc and the sharpness of the transition is proportional to the degree of interconnectivity of grains [2,4]. The observed effect indicates a better quality of the prepared samples. By applying the magnetic field, the increase of the magnetic field.

**Fig.1.** Temperature dependence of the resistivity for the micro-bridges  $YBa_2Cu_3O_{7-\delta}$  : (a)10 µm×575µm , (b)50 µm×575 µm, (c)100 µm×300 µm at different applied fields and the current of 100 µA.

**Fig.2.** Evolution of the width of resistive transition $\Delta T = T_{c, onset} - T_{c, offset}$  for different micro- bridges of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7.8</sub>

**Table 1.**The values of critical transition temperatures ( $T_{c \text{ onset}}$  and  $T_{c \text{ offset}}$ ) and the temperature width ( $\Delta T$ ) for the microbridges YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7- $\delta$ </sub>: (a) 10 $\mu$ m×575 $\mu$ m, (b) 50 $\mu$ m×575 $\mu$ m, (c) 100 $\mu$ m×300 $\mu$ m at different applied fields and the current of 100  $\mu$ A.

В	<b>0</b> T	<b>2</b> T	<b>7</b> T
$\begin{array}{l} \textbf{Bridge1} \\ T_{c,onset}(K) \\ T_{c,offset}(K) \\ \Delta T (K) \end{array}$	90,30	91,95	91.82
	88,30	83,01	77,55
	2,00	8,94	14,27
Bridge2 $T_{c,onset}(K)$ $T_{c,offset}(K)$ $\Delta T (K)$	90,96 88,41 2,55	91,86 80,02 11,84	92,24 77,63 14,66
$\begin{array}{c} \textbf{Bridge3} \\ T_{c,onset}(K) \\ T_{c,offset}(K) \\ \Delta T (K) \end{array}$	90,50	90,98	91,88
	88,41	82,96	77,50
	2,09	8,02	14,37

As shown in Table 1 and Figure 2, for each sample,  $T_{c, offset}$  goes to lower values on increasing the magnetic field, resulting in a wider resistive transition  $\Delta T$  ( $\Delta T = T_{c,onset} - T_{c,offset}$ )[2,10]. The width  $\Delta T$  of superconducting transition temperatures of the micro bridges' samples in a 7 T magnetic field appears to be nearly 14K. This effect is owed to the looseness of superconducting current paths.

Indeed, the larger number of grain boundaries and weak bonds among superconducting grains is, the wider  $\Delta T$  will be [10,11]. The tailing behaviour is known to be correlated with the high thermal energy of vortices and the disorders in the percolation path among grains owing to different directions in polycrystalline compounds [3]. This leads to the weakening of flux pinning strength and as a result, a more resistive state occurs [1,2].

#### 3.2 Activation energy

The transition region broadening under different magnetic fields can be examined in terms of activation energy of the vortex according to the law of Arrhenius [12–14]:

$$\rho(B,T) = \rho_0 e^{\frac{-U(B,T)}{K_B T}}$$

Where  $\rho_0$  is the normal resistivity, U (B, T) is the activation energy for flux creep that depends on the temperature and magnetic field and kB is the Boltzmann constant. For the case of classical flux creep, where U >>k<sub>B</sub>T, the activation energy should not depend on temperature and the resistivity behaves as[2,14]:

$$\rho(B,T) = \rho_0 e^{\frac{-U_0}{K_B T}}$$

Under this assumption, we can obtain the relation:

$$ln\rho(B,T) = ln\rho_0 - \frac{U_0(B)}{K_B T^{(3)}}$$

From this relation,  $ln\rho$  is linear to 1/T, which is called an Arrhenius relation. The activation energy U<sub>0</sub> values can be directly deduced by calculating the slope of each curve in the low resistivity regime presented in Figure 3 and Table 2 [15].

**Fig.3**.Ln( $\rho$ ) versus 1/T graphs of the micro- bridges of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7- $\delta$ </sub> : (a) 10 $\mu$ m×575 $\mu$ m, (b) 50  $\mu$ m×575 $\mu$ m, (c) 100 $\mu$ m×300 $\mu$ m at different applied fields and the current of 100 $\mu$ A.

Table 2. Activation energy for the micro-bridges of<br/>YBa2Cu3O7.8 : (a)  $10\mu$ m×575µm, (b)50µm×575µm,(c) $100\mu$ m×300µm at different applied fields and the current of<br/> $100\mu$ A.

Activation energy (eV)					
В	0T	2T	7T		
Bridge1	10,52	1,12	0,69		
Bridge2	8,52	1,14	0,82		
Bridge3	9,54	1,09	0,77		

It is seen that the superconducting transition curve is fairly vertical and sharp at a 0 T magnetic field. As the applied magnetic field increases, the transition width expands. With the decline in slope of  $\ln \rho(T)$  versus 1/T, therefore the activation energy will decrease. The resistive transition in the Arrhenius plot appears curved. This curvature was explained first phenomenologically by Palstra et al. [16] who explained the field dependence of dissipative flux motion from the slope of the Arrhenius plot.

Fig.4. The change of the activation energy values of the micro- bridges of  $YBa_2Cu_3O_{7-\delta}$  with the applied magnetic field up to 7 T

As seen in Figure 4, the decrease of the activation energy depending on the increasing magnetic field causes vortex motion easily.

Activation energy

According to the vortex-glass theory, the resistivity in the flux–flow liquid region should approach zero as the temperature approaches the glass temperature Tg following a power-law behaviour[17,18]:

$$\rho \propto (T - T_g)^{s}_{(4)}$$
  
Where s is the exponent related to the vortex-glass correlation.

From this law we can use the relation:

temperature indicating the vortex-glass phase unsition obtained from T-axis intercept of 
$$\left[\frac{d\left(\frac{ln\rho}{dT}\right)}{s}\right]^{-1} \propto \frac{T-T_g}{s}$$
 (5) temperature indicating the vortex-glass phase unsition obtained from T-axis intercept of  $\left[\frac{n\rho}{dT}\right]^{-1}$  versus T plot[19,20].

As shown in Figure 5, the estimated vortex glass transition temperature  $T_g$  for different magnetic fields is shown in Table 3.

**Fig.5**.  $d(\ln R)/d(1/T)$  as a function of temperature in different magnetic fields: (a)  $10\mu m \times 575\mu m$ , (b)50  $\mu m \times 575\mu m$ , (c)  $100\mu m \times 300\mu m$  at different applied fields and the current of  $100\mu A$ .

**Table 3.**The values of vortex-glass temperature for the micro-bridges of YBa2Cu3O7-δ : (a) 10μm×575μm, (b) 50μm×575μm, (c) 100 μm×300μm at different applied fields and the current of 100μA.

vortex-glass temperature T <sub>g</sub>				
В	0Т	2T	7T

Bridge2	88,82	80,21	78,55	
Bridge3	88,70	82,38	78,82	

The B<sub>irr</sub> and B<sub>c2</sub> are estimated from the resistivity versus the applied magnetic field curves. As it is well known from the literature [5,8], at various magnetic fields, the Birr and Bc2 are defined as the fields where the temperature-dependent resistance is  $\rho(B_{c2},T) = 90\%\rho_n$  and  $(B_{irr},T) = 10\%\rho_n$ , where pn indicates the normal state resistance of the samples at Tc, onset. From Figure 1, the Bc2 and the Birr were determined by the usual criterion of 90% and 10% of the normal state resistivity, respectively. The obtained values are tabulated in Table 4.

**Table 4.**B<sub>irr</sub>, B<sub>c2</sub> and T values from magneto resistivity measurement for the micro-bridges of  $YBa_2Cu_3O_{7-\delta}$ : (a)  $10\mu m \times 575\mu m$ , (b)  $50\ \mu m \times 575\mu m$ , (c)  $100\mu m \times 300\mu m$ .

В	0T	2T	7T
<b>Bridge1</b> <i>T<sub>c2,90%</sub>(K)</i> <i>T<sub>irr,10%</sub>(K)</i>	90,21 88,51	89,82 85,12	88,07 80.14
<b>Bridge2</b> <i>T<sub>c2,90%</sub>(K)</i> <i>T<sub>irr,10%</sub>(K)</i>	90,17 88,66	88,44 82,57	87,42 80,19
<b>Bridge3</b> <i>T</i> <sub>c2,90%</sub> ( <i>K</i> ) <i>T</i> <sub><i>i</i>rr,10%</sub> ( <i>K</i> )	89,90 88,65	89,05 85,16	87,68 80,19

We finally display in figure 6 the phase diagram constructed from values of  $T_g(B)$ ,  $T_{irr}(B)$  and  $T_{c2}(B)$  obtained for our sample, showing the vortex glass, the irreversibility line, the vortex liquid and normal state [6,21]. The vortex liquid phase exists above vortex glass phase and is confined between  $B(T_g)$  and  $B_{c2}$ . Though a clear vortex liquid phase is observed, as it is well known from the literature that [21,22] for fields, B >  $B_{c1}$  there is a kind of competition between thermal fluctuations and the repulsive inter-vortex interaction. As the temperature increases, the thermal fluctuations dominate resulting in the formation of vortex liquid phase.

**Fig.6** .Magnetic phase diagram obtained from this work for the micro-bridges of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7- $\delta$ </sub> : (a) 10 $\mu$ m×575 $\mu$ m, (b) 50 $\mu$ m×575 $\mu$ m, (c) 100 $\mu$ m×300 $\mu$ m at different applied fields and the current of 100 $\mu$ A.

## 4 Conclusions

In conclusion, we report the magneto-resistivity of three micro bridges of samples  $YBa_2Cu_3O_{7-\delta}$ . The broadening of the resistive transition under a magnetic field was observed and it can be described in the frame of the flux motion mechanism. From magneto-resistivity measurements, the activation energy  $U_0$ , the upper critical field  $B_{c2}(0)$  and irreversibly field  $B_{irr}$  were calculated. The vortex phase diagram of  $YBa_2Cu_3O_{7-\delta}$  is presented using these results. A very broad vortex-liquid phase regime is found to exist in the vortex phase diagram of  $YBa_2Cu_3O_{7-\delta}$ .
